ABSTRACT:
Background: Childhood obesity is increasingly being observed with the changing lifestyle. There are a few studies, reporting, prevalence of childhood and adolescent obesity and overweight from different parts of India that range from 3% to 29%, and also indicate that the prevalence is higher in urban than in rural areas. Hence; the present study was planned to assess correlation between overweight and dental caries among school children. Materials & methods: The present investigation included assessment of correlation between overweight and dental caries among school children. A total of 500 school going children between the age group of 9 to 14 years were included in the present study. Complete demographic and clinical data of all the subjects was obtained. For collecting the information, a predesigned proforma was used. Body weight, height and waist circumference of all the subjects was recorded and were divided into following categories: Underweight, Normal weight, Risk of overweight and overweight. All the results obtained were compiled and analyzed by SPSS software. Results: There were 120 normal weight males and 120 normal weight females. Overweight subjects had significantly higher DMFT/dmft score in comparison to normal weight subjects (P-value < 0.05). Conclusion: Overweight school children are associated with significantly higher prevalence of dental carries.

Key words: Dental caries, Obesity, School children

INTRODUCTION
Childhood obesity is increasingly being observed with the changing lifestyle of families with increased purchasing power, increasing hours of inactivity due to television, video games, and computers, which are replacing outdoor games and other social activities.¹² Studies conducted in many parts of the world have shown physical inactivity including lack of participation in sports activities at school or at home, and less active mode of transport to and from school to be associated with increased risk of overweight and obesity among children [3–5]. Diets high in saturated fats, sugars and refined starch have also been shown to contribute to the increasing overweight and obesity among children and adults.³⁵ There are a few studies, reporting, prevalence of childhood and adolescent obesity and overweight from different parts of India (Punjab, Maharashtra, Delhi and South India) that range from 3% to 29%, and also indicate that the prevalence is higher in urban than in rural areas.⁶⁸ Hence; the present study was planned to assess correlation between overweight and dental caries among school children. Materials & methods: The present investigation was conducted in the department of public health dentistry of the dental institute and it included assessment of correlation between overweight and dental caries among school children. A total of 500 school children in Jammu city were included in the present study. Complete demographic and clinical data of all the subjects was obtained. For collecting the information, a predesigned proforma was used. Body weight, height and waist circumference of all the subjects was recorded and were divided into following categories: Underweight, Normal weight, Risk of overweight and overweight. All the results obtained were compiled and analyzed by SPSS software. Results: There were 120 normal weight males and 120 normal weight females. Overweight subjects had significantly higher DMFT/dmft score in comparison to normal weight subjects (P-value < 0.05). Conclusion: Overweight school children are associated with significantly higher prevalence of dental carries.
going children between the age group of 9 to 14 years were included in the present study. Ethical approval was obtained from institutional ethical committee, and written consent was obtained from all the guardians of all the pediatric subjects. Complete demographic and clinical data of all the subjects was obtained. For collecting the information, a predesigned proforma was used. Modified Kuppuswamy's Socio-economic status (SES) was used for assessing the SES of the subjects.\(^1\) Criteria defined by WHO was used for defining and recording dental caries in subjects.\(^1\) Body weight, height and waist circumference of all the subjects was recorded and based on the criteria previously described previously in the literature, they were divided into following categories:\(^1\)

- Underweight
- Normal weight
- Risk of overweight
- Overweight

All the results obtained were compiled and analyzed by SPSS software. Chi-square test was used for assessment of level of significance.

RESULTS
A total of 500 subjects were included in the present study. There were 300 males and 200 females. Mean age of the males and females in the present study was 11.2 years and 10.5 years respectively. There were 50 underweight males and 40 underweight females. There were 120 normal weight males and 120 normal weight females. Overweight subjects had significantly higher DMFT/dmft score in comparison to normal weight subjects (P-value < 0.05).

DISCUSSION
In the present study, there were 300 males and 200 females. Mean age of the males and females in the present study was 11.2 years and 10.5 years respectively. There were 50 underweight males and 40 underweight females. There were 120 normal weight males and 120 normal weight females. Overweight subjects had significantly higher DMFT/dmft score in comparison to normal weight subjects (P-value < 0.05).

Mahajan PB et al studied prevalence of obesity and overweight among school children in Puducherry. To identify any variation as per age, gender, place of residence and type of school. Children between 6 and 12 yrs were sampled using multistage random sampling with population proportionate to size from 30 clusters. Anthropometric data (BMI) was analyzed using CDC growth charts. Data was analyzed using SPSS, BMI (CDC) calculator, CI calculator and OR calculator. The prevalence of overweight (≥85th percentile) among children was 4.41% and prevalence of obesity (>95th percentile) was 2.12%. Mahaj region had the highest prevalence of overweight (8.66%) and obesity (4.69%). Female children from private schools and urban areas were at greater risk of being overweight and obese. Childhood obesity is a problem in Puducherry and requires timely intervention for its control.\(^1\) Mwaikambo SA et al determined the prevalence and factors associated with overweight and obesity in 1722 children aged 7–14 years (10.9 ± 1.74) attending primary schools in Dar es Salaam. Six public and four private schools were systemically selected from a total of 227 primary schools. Anthropometric measurements (weight and height) were collected using a standard protocol and Body Mass Index (BMI) was calculated. Interviews collected demographic characteristics and lifestyle factors. Multiple logistic
regression test was used to assess the influence of independent variables on overweight and obesity while controlling for confounding factors. The level of significance was set at $\alpha = 5\%$. Of 1,722 children 10.2 % were overweight and 4.5 % were obese. Overweight and obesity was higher in boys (14.9 %) than girls (14.5 %), higher in children attending private schools (27.7 %) than public schools (5.9 %). Children who walked to and from school were less likely to be overweight or obese than those who used vehicles ($\text{AOR} = 0.5; 95\%\text{CI}: 0.3$–$0.6; p < 0.001$). Those who used private cars or school buses were more likely to be overweight or obese than those who used public transport ($\text{AOR} = 2.9; 95\%\text{CI}: 0.2$–$7.3; p = 0.03$). Lunch provided by schools was associated with increased risk of overweight or obesity (AOR = 6.4, 95% CI = 4.2–9.6, $p < 0.001$). The findings of this study identified a number of behavioural and dietary factors that are related to overweight and obesity.\(^{15}\)

**Conclusion**
Under the light of above obtained data, the authors conclude that overweight school children are associated with significantly higher prevalence of dental carries. However; further studies are recommended.
